

Chapter 2

Data Types

SystemVerilog offers many improved data structures compared with Verilog. Some of these were created for designers but are also useful for testbenches. In this chapter you will learn about the data structures most useful for verification.

SystemVerilog introduces new data types with the following benefits.

- Two-state: better performance, reduced memory usage
- Queues, dynamic and associative arrays: reduced memory usage, built-in support for searching and sorting
- Classes and structures: support for abstract data structures
- Unions and packed structures: allow multiple views of the same data
- Strings: built-in string support
- Enumerated types: code is easier to write and understand

2.1 Built-In Data Types

Verilog-1995 has two basic data types: variables and nets, both which hold 4-state values: 0, 1, Z, and X. RTL code uses variables to store combinational and sequential values. Variables can be unsigned single or multi-bit (`reg [7:0] m`), signed 32-bit variables (`integer`), unsigned 64-bit variables (`time`), and floating point numbers (`real`). Variables can be grouped together into arrays that have a fixed size. A net is used to connect parts of a design such as gate primitives and module instances. Nets come in many flavors, but most designers use scalar and vector wires to connect
